Appendix A. Survey validation..... 42

Fairfax County Results from the Virginia Community Youth Survey

Fairfax County Results from the Virginia Community Youth Survey includes data collected as part of the Virginia Community Youth Survey initiative sponsored by the Commonwealth of Virginia. The goal of the study is to provide information about youth behaviors – those that are positive as well as those that are harmful. These data are often referred to as risk and asset data and provide insight into the prevalence and frequency of substance abuse, antisocial behaviors and positive behaviors. These data provide Fairfax County with a barometer of the effectiveness of our community in fostering healthy choices in our youth.

The 2003 survey queried Fairfax County Public School students in 8th, 10th and 12th grade. Classes were randomly selected by grade from English classes. The target sample represented approximately 15 percent of the student membership in the grades sampled. The survey was administered in classroom settings and took approximately one class period to complete. Students were informed that the study was voluntary and that they could opt out of the entire study or skip individual answers they did not feel comfortable answering. Both teacher and written instructions on the front of the questionnaire assured students that their answers would be kept strictly confidential.

A total of 4,239 questionnaires were completed by students, representing nearly 13 percent of the total student membership in grades 8th, 10th and 12th grade as of January 2004. The data set received from the state contained 4,092 survey observations. The state deleted 147 observations based on the validity checks they conducted (missing grade, wrong grade, derbisol use, etc.) An additional 18 observations were deleted by Fairfax County based on validity checks conducted bringing the valid number of observations to 4,074. Table 1 provides detail on how many students were removed from the study based on validity checks and shows some of the demographic characteristics of the students participating in the survey. How these validity checks were conducted are discussed in greater detail in the survey validation section.

The survey measured a variety of demographic characteristics. Throughout this report, results are presented individually for each grade level, gender and ethnicity. Also note that percentages may not equal 100 percent because not all students responded to all questions.

For Fairfax County, a slightly higher percentage of the respondents were male (47.1 percent male compared to 45.4 percent female). Table 1 shows the racial/ethnic breakdown of the surveyed population of Fairfax County. A majority of students identified themselves as not Hispanic White (52.7 percent). The largest minority population is Asian or Pacific Islander (17.7 percent). Hispanics or Latinos make up 12.2 percent of the respondents, not Hispanic Blacks or African Americans are 9.5 percent, and the remaining 7.9 percent are other races, multiracial or did not respond to the racial/ethnicity questions.

Survey Validation

The 2003 survey instrument was similar to that used for the 2001 Fairfax County *Communities That Care® Youth Survey*. These survey instruments are based on research funded by the Center for Substance Abuse Prevention (CSAP) at the U.S. Department of Health and Human Services and follow nationally set protocols and standards. The surveys provide extremely valuable information, but users of this information need to be aware of issues that may affect the interpretation and comparison the findings from these surveys. These issues can be loosely categorized into three areas – differences between the two survey instruments, challenges associated with collecting data on sensitive topics and sampling issues. See Appendix A for details.

Table 1. Selected demographic characteristics of surveyed youth.

Honesty	23	0.5%
High Use	20	0.5%
No Grade or Wrong Grade	20	0.5%
Too Much Missing Data	63	1.5%

Notes: "Number of Students: represents the number of students that participated in the Fairfax County survey, by grade, sex, and ethnicity. "Percent of students" indicates the percentage of the overall population represented by students in that category.

Five strategies are used to assess the validity of the surveys. The "Ineligible" section shows the percentage of students who were eliminated under each disqualifying criteria and the total number of students who were removed from the data analysis.

A total number of participating students can be obtained from adding "overall valid cases" and "ineligible students- total."

Table 2. Selected characteristics of the home life of surveyed youth, by grade, sex, and ethnicity.

LSD or Other Psychedelics ¹	77	2.0%	169	4.6%	412	12.2%	9	0.6%	49	3.4%	88	7.8%

Notes: Percents may not sum to 100% due to rounding. 'N' represents the valid number of cases, by category, that reported use for a given survey item, and '%' represents the percentage of valid cases, by category, that reported use for a given survey item. The question on cocaine differs in the two surveys. The 2003 survey asks 'have you used cocaine or crack' while the 2001 survey asks only about cocaine.

¹ Based on the Cochran-Mantel-Haenszel chi-square statistic, an association exists between year and usage levels controlling for the effects of grade and gender. ($\alpha=0.001$ level of significance).

¹Binge drinking is defined as five or more drinks in a row in the last two weeks. The Monitoring the Future survey asked about binge drinking over the past two weeks in 2001 but changed the question to 'have been drunk or very high from drinking in the past 30 days' in 2002. The different wording of the questions give different results and are not comparable.

²The Monitoring the Future surveys asked about both marijuana and hashish whereas the Fairfax surveys asked only about marijuana.

Notes: Percents may not sum to 100% due to rounding. Sample sizes on distributions and means are frequently small and may not be representative. Racial categories do not include Hispanic persons as they are treated as a separate category in this table. Binge drinking is defined as five or more drinks in a row in the last two weeks.

* The "Average Number of Occasions" column shows the average number of times that a group reported involvement during the past 2 weeks and includes only those who indicated at least one occasion of the behavior. The two prevalence categories ("Never" and "Any Occasion") sum to 100% and represent the total number of valid cases for the survey question. The "Number of Occasions" categories sum to the "Any Occasion" category.

Table 10. Lifetime and thirty-day prevalence for cigarettes, by selected demographic characteristics.

	Lifetime N	Lifetime %	30-Day N	30-Day %
Overall Valid Cases	1,290	32.1%	542	13.5%

Appendix A. Survey validation.

Survey Instrument Differences – Not all of the questions on the 2001 questionnaire were included on the 2003 questionnaire. Wording, layout and instructions, although similar, were not always identical between the two instruments. Therefore, some variation beyond what might be statistically expected may be due to students interpreting answer categories and questions differently between the two years. Examples of some of these differences include:

- The 2001 instrument gave explicit instructions on how to interpret the 'YES,' 'yes,' 'no,' 'NO' answer format; the 2003 instrument did not provide these instructions.
- Many of the questions with Likert scale answer categories (i.e. very important, quite important, fairly important, slightly important, not at all important) on the 2003 instrument have a mixed horizontal and vertical layout that makes it difficult to determine the flow of the answer categories.
- Questions have wording differences – 'On how many occasions (if any) have you used cocaine *or crack* in your lifetime?' (2003) compared to 'On how many occasions (if any) have you used cocaine in your lifetime?' 'My teachers praise me when I *have done well* in school (2003).' compared to 'My teachers praise me when I *work hard* in school (2002).'

Sensitive Topics – Most people feel some degree of discomfort when asked to respond to highly sensitive topic areas such as substance abuse and antisocial behaviors. Therefore, it is not unusual to have some degree of ambiguity in the results of surveys that measure these types of behaviors. Even when respondents are assured confidentiality, they are often reluctant to tell the truth or may feel pressure to respond in a socially acceptable manner. The cleaning and validation protocols associated with the 2003 instrument help reduce some of these inconsistencies. The protocols used to assess validity on the 2003 data are similar to those used on the 2001 data. These protocols can be grouped into those that determine the validity of individual surveys and those that correct inconsistencies between questions of an individual survey.

- The following protocols were used to determine the validity of individual surveys.
 - Students who reported they were in a grade other than 8th, 10th or 12th grade or did not answer the grade question were deleted from the data set and not included in the analysis of findings.
 - Students who reported using the fictitious drug *derbisol* were deleted from the data set and were not included in the analysis of findings.
 - Students who indicated an unrealistic use of substances during a 30 day period were removed from the data set. Specifically, the strategy was to identify surveys with an unrealistic past 30-day use of marijuana, LSD or other psychedelics, cocaine or crack, and inhalants (alcohol, tobacco, and methamphetamines were not included in this strategy). If the survey indicated past 30-day use on 40 or more occasions, the category of greatest use, on three or more questions, the survey was considered invalid.
 - Students who answered the final question (How honest were you in filling out this survey?) with the most extreme response (I was not honest at all) were removed from the analysis data set.
 - Students who had missing data on all of the questions on which validity checks were performed were removed from the analysis data set.
- The following protocols were used to correct inconsistencies between answers within an individual survey.

- Students who reported a greater 30-day use than lifetime use of a substance had their lifetime use recoded to equal the 30-day use. This is a standard practice in resolving consistency between short-term and long-term memory items and has been incorporated into the data cleaning process for this instrument in other CSAP-funded needs assessment states.
- Students who answered that they had never belonged to a gang in both questions 30 and 38 but indicated their gang had no name in question 39 had their answers to question 39 recoded to 'I have never belonged to a gang.'

In addition other inconsistencies between questions were identified but no attempt was made to resolve these inconsistencies because no national protocols have been established. The inconsistencies identified include:

- Students who had inconsistent answers to whether they had siblings on question 5 (Think of where you live most of the time. Which of the following people live there with you?), question 6 (How many brothers and sisters including stepbrothers and stepsisters do you have that are older than you?), question 7 (How many brothers and sisters including stepbrothers and stepsisters do you have that are younger than you?), and question 103 (Have any of your brothers or sisters ever...?). For example indicating that they lived with a sibling on question 5, but reporting no siblings older or younger than themselves on questions 6 and 7. Some of this inconsistency may occur because perhaps twins consider themselves the same age as their sibling and the answer categories on the survey do not allow for this option.
- Students who had inconsistent answers to question 30 (How old were you when you first...?) and question 40 (How many times in the past year have you...?) on the following items – suspension from school, carried a handgun, taken a handgun to school, got arrested, and/or attacked someone with the idea of seriously hurting them. For example in question 40 they indicated being suspended from school one or more times but answered question 30 that they 'Never Have' been suspended from school.
- Students who answered inconsistently between question 30 (How old were you when you first belonged to a gang?) and question 38 (Have you ever belonged to a gang?).
- Students who answered inconsistently between question 30 (How old were you when you first smoked a cigarette, even just a puff?) and question 55 (Have you ever smoked cigarettes?). Some of this inconsistency may be due to the phrase '*even just a puff*' in question 30 because students may not associate a puff or two with cigarette smoking in question 55.
- Students who answered inconsistently between question 30 (How old were you when you first smoked marijuana?) and question 60 (On how many occasions, if any, have you used marijuana in your lifetime?). Some of this inconsistency may be due to question wording – question 30 asks about *smoking* while question 60 asks about *use*.

- Students who answered inconsistently on one or more of the alcohol questions.
 - Question 30C (How old were you when you first had more than a sip or two of beer, wine, or hard liquor),
 - Question 30D (How old were you when you first began drinking alcoholic beverages regularly, that is, at least once or twice a month?),
 - Question 57 (On how many occasions have you had beer, wine, or hard liquor to drink in your lifetime, more than just a few sips?), and
 - Question 59 (Think back over the last two weeks. How many times have you had five or more alcoholic drinks in a row?).

Excluding the sibling inconsistencies, 654 surveys or 16 percent contained one or more of these inconsistencies with the vast majority containing only one inconsistency (586 surveys). In comparison, 19 percent of the 2001 surveys were affected by one or more of these internal inconsistencies. Thus, the level of inconsistency has been relatively constant from 2001 to 2003. It is not possible to easily measure the direct effect these inconsistencies have on the survey estimates but it is important to keep these limitations in mind when interpreting the data. That is, the results from these surveys are estimates and provide barometers for detecting trends.

Sampling Issues – Care must be taken when comparing the results between the 2001 and 2003 surveys. Two surveys of the same items on samples of the same population will rarely yield exactly the same results, but repeated measurements should be consistent from measurement to measurement if the data are reliable. When studies are repeated on different populations, such as in this case, comparisons are made more difficult as characteristics which influence the results may change in the populations over time. Grade level and gender are two of the stronger influences tied to substance abuse and antisocial behavior. The 2003 survey population contains a higher proportion of 8th and 10th graders than the 2001 survey population and the 2003 survey population contains a slightly greater proportion of males. Thus on the gang membership question and the lifetime and 30-day usage questions, statistical tests have been conducted to determine which of these items show statistical differences between the two survey years when controlling for grade and gender.¹ In conducting and interpreting these statistical tests, it is assumed that the changes in the survey instruments (wording, layout and instructions) have no effect on the results. Given that assumption, there was no association between year and gang membership ($\alpha=0.001$ level of significance). Tables 3 and 4, showing the 2001 and 2003 results for the lifetime and 30-day usage items, contain notes indicating if there is an association between year and usage levels for these items.

¹ Tests of association controlling for gender and grade level were conducted using the Cochran-Mantel-Haenszel statistic. The Cochran-Mantel-Haenszel procedure produces statistics for categorical data that detect general association controlling for strata. It removes the confounding influence of the explanatory variables that comprise the stratification and provides a gain of power for detecting association by comparing like subjects.
